

ABSTRACT OF THE DISCLOSURE

An improved tie system for organizing and detachably securing moveable articles comprises a folding tie. The tie includes a foldable support element (20) having opposing sides and having both a male fastener patch (22) and a female fastener patch (23) such as hook-and-loop fasteners, on both opposing sides. Two fastener patches of complementary gender are located opposite one or more folding zones (24). The tie folds to enfold one or more articles (27) and detachably engages male and female fastener elements located on the same side of the support element. Upon folding the tie, the fastener elements of the tie engage in a releasable couple, and an article is thereby held and secured inside the fold. The folded tie may be collected with others of its own kind, in weakly-secure clusters, and also may be anchored and labeled.
